ABSTRACT/RÉSUMÉ

This paper provides new projections on the fiscal impact of age-related spending for OECD countries over the next half century. These results are based on national models using an agreed upon set of assumptions about macroeconomic and demographic developments for all countries. Recent reforms to pension systems have partly offset the impact on spending of an increasingly elderly population, and there has been a major improvement in the underlying fiscal situation in the 1990s. However, further age-related spending (including old age pensions, health and spending associated with children) is still projected to increase on average around 6 to 7 per cent of GDP over the projection period. This calls for maintaining the reform effort and intensifying it in several countries, if fiscal sustainability is to be maintained.

JEL classification: I1, I3, J1, J11, J14, J26

Keywords: Ageing populations, pensions, health care, long-term projections

Cette étude contient de nouvelles projections sur l'impact budgétaire des dépenses liées à l'âge dans les pays de l'OCDE pour les cinquante prochaines années. Ces résultats reposent sur des modèles nationaux utilisant un cadre macroéconomique et démographique normalisé pour tous les pays. Les réformes récentes des régimes de retraite ont compensé en partie l'incidence du vieillissement de la population sur les dépenses et les situations budgétaires sous-jacentes se sont nettement améliorées dans les années 90. Toutefois, les dépenses liées à l'âge (c'est-à-dire aux pensions de vieillesse, à la santé et aux enfants) devraient augmenter en moyenne de 6 à 7 pour cent du PIB au cours de la période de projection. Il est donc nécessaire de maintenir les efforts de réforme et de les intensifier dans plusieurs pays si l'on veut préserver la viabilité budgétaire.

Classification JEL : I1, I3, J1, J11, J14, J26

Mots-clés : vieillissement de la population, pensions de retraite, soins de santé, projections à long terme

FISCAL IMPLICATIONS OF AGEING: PROJECTIONS OF AGE-RELATED SPENDING

Thai Than Dang, Pablo Antolin and Howard Oxley¹

Introduction

1. The combination of the baby boom in the early post-war period, the subsequent fall in fertility rates from the end of the 1960s and increasing life expectancy are leading to a progressive ageing of the population in virtually all OECD countries. This will begin to affect public finances significantly as the baby-boom generation progressively reaches retirement age over the next few decades. The impact of these developments on public finances is an issue of concern and debate in most OECD countries, and a substantial number of policy reforms have been introduced over the past decade. This paper reviews these public finance developments on the basis of more up-to-date estimates covering the next half-century. The estimates are based on results generated by Member countries, using the models of national administrations or research institutes in order to ensure that better account is taken of institutional detail affecting expenditures than has been possible in previous OECD work.² At the same time, consistency and comparability across countries have been strengthened by using a set of population projections and common assumptions for establishing GDP growth and other key macroeconomic variables that were agreed between countries and the OECD Secretariat. Because of the wide margins of uncertainty over such a long time horizon, sensitivity tests are also provided which show the impact of changes to key assumptions. On the basis of these results, the paper then assesses the need for further reforms and which kinds of reforms are likely to have the greatest impact on budget outcomes.³

2. A number of considerations need to be kept in mind when interpreting the results. First, the OECD Secretariat has helped co-ordinate the preparation of the results, with the actual projections based on the work of national experts using their own models. This approach differs from previous OECD exercises -- where a standardised modelling approach was used -- but, as noted, has the advantage of providing richer institutional detail. Further, the OECD Secretariat has not controlled the use of underlying assumptions within the models beyond those agreed by the participating countries (population and the macroeconomic environment). While the OECD Secretariat believes that a reasonable degree of uniformity has been obtained, complete consistency across countries in assumptions and approach has not necessarily been achieved. Second, it should also be noted that the projections presented below may differ from those

1. This work presented in this paper has been based on the replies to OECD questionnaires from national authorities and research teams of the reporting countries. The authors would like to express their appreciation for the time, effort and attention that they devoted to this project. The authors would also like to thank Jørgen Elmeskov, Mike Feiner, Nicholas Vanston and Ignazio Visco for their helpful comments and suggestions. Special thanks go to Mark Kircher for statistical assistance and Paula Simonin and Charlotte Todd for secretarial skills. The views expressed in this Working Paper are those of the authors and are not necessarily shared by the OECD.

2. See Hagemann and Nicoletti (1989), Van den Noord and Herd (1993, 1994), Leibfritz *et al.* (1995), Roseveare *et al.* (1996), OECD (1997, 1998 and 2000), Turner *et al.* (1998) and Visco (2000, 2001).

3. Part of this work has been carried out in collaboration with the Working Group on Ageing of the Economic Policy Committee of the European Union. Their study as well as this one are based on the same macroeconomic framework and population projections. However, the public expenditure components covered as well as the timing of the studies have differed somewhat. Preliminary results for the EU countries were presented in Economic Policy Committee of the European Union (2000).

used by national administrations in their “most likely” scenarios, because of differences in assumptions. Third, in any case, projections over such a long period are, by their nature, highly uncertain as economies will evolve and policies will change in ways that cannot be foreseen.

The baseline projections

Underlying assumptions

3. Estimates of the degree of ageing over the next 50 years were based on the middle variant of Eurostat population projections for the countries in the European Union (EU) and national projections for the remaining countries. While there is considerable cross-country variation, these projections show an average increase in fertility of around 8 per cent and a lengthening in average lifetimes of about 4½ years (Table 1). Generally speaking, these developments lead over the period as a whole to:

- Very modest growth or declines in the total population (except in Australia, Canada, the Netherlands, New Zealand, Norway and the United States).
- A fall in the working age population (20 to 64 years of age) (except in Australia, Canada, New Zealand, Norway, and the United States), and, increases in the number of elderly and, particularly, in those over 80 (Table 2).
- A near doubling, on average, in the ratio of the elderly (individuals 65+) to the working-age population (individuals 20-64) between 2000 and mid-century (the old-age dependency ratio) (Figure 1). For most countries, the ratio is projected to increase until about 2035 to 2045 (depending on the country), and then to stabilise or decline by a small amount thereafter. However, in Australia, the Czech Republic, Hungary, Japan, Poland, Spain, and, to a lesser degree, Canada and Korea, ageing appears to be increasing even at the end of the period, suggesting that these countries may experience further pressures on spending from ageing beyond 2050.
- A rise in the average age both of the working-age population and of the elderly, *i.e.* both the share of those aged 55 to 64 in the population aged 20 to 64 and the share of the very old (aged 80+) among the elderly (aged 65+) increase (Table 2). This latter development reflects the passing of the baby-boom generation and longer life expectancy.
- In contrast, a small decline in the ratio of youth (individuals less than 20) to the working-age population, suggesting some minor offsetting declines in spending on children (Table 2).

4. The common assumptions on unemployment and participation rates (Box 1) imply that countries that now have high rates of unemployment relative to the OECD average and low participation rates of women (*e.g.* Italy and Spain) have more scope for growth over the period. In practice, however, the declines projected for the working-age population offset such effects in most countries and average employment growth over the period is either weakly positive or negative except in Australia and the United States.

5. Almost all of the GDP growth -- which averages 1.9 per cent annually -- is due to the increase in labour productivity (Figure 2), which was set to converge, to a trend rate of 1¾ per cent per annum (see Box 1 for details). Some catch-up was allowed for the Czech Republic, Hungary, Korea, Poland and Portugal and, therefore, their productivity growth rates are significantly above those of the other countries.

Finland starts from high productivity growth rates to converge by 2020. Norway and Canada to a lesser extent, show low growth rate in productivity as they start from low productivity growth rates. In addition, Norway's projections reflect the impact of the oil sector.

Box 1. Population projections and background assumptions¹

Population projections

Projections were based on the middle variant of national or, in the case of EU countries, Eurostat population projections. The profile of populations over time in these projections depends on assumptions about fertility, mortality and immigration (see Table 1). The Eurostat population projections were specially prepared for this exercise.

Fertility

In virtually all countries fertility rates are projected to rise from an average of around 1.5 towards levels ranging between 1.5 and 1.8 by 2050, with most of the increase occurring over the next two decades. The largest increases are expected to occur in low-fertility countries such as the Czech Republic, Italy and Spain but increases are also substantial in Austria, Belgium, Hungary, Japan, Poland, Portugal and Sweden. Denmark, Finland and Norway are assumed to have fairly constant fertility rates. Only Australia, Canada, Korea, New Zealand and the United States are projected to experience significant declines.

Life expectancy

Life expectancy at birth is expected to increase, on average, by above 5 years for males and 4 years for females from 2000 to 2050, thus allowing some catch-up between the two sexes. Gains in life expectancy are similar across the majority of countries, although they are smaller for men in the Czech Republic and Japan and higher in Hungary and Poland, which both have a particularly low level at the beginning of the period. For women, the increases are smaller in Canada, the Czech Republic, Japan, Norway and Spain and significantly higher in Australia, Hungary, Korea, Poland and the United Kingdom.

Net immigration

Net immigration is difficult to predict since it will depend on countries' economic situation and policies. Countries with higher levels of immigration at the beginning of the period tend to project falls (Australia, Canada, Germany, Norway and the United States), while a number of countries with low levels project increases (Austria, Belgium, Italy and Spain). Once again, changes tend to be concentrated in the first half of the period.

Implications for dependency

These various developments contribute to the flattening in the dependency ratios toward the middle of the century. The replacement of the baby-boom generation by smaller cohorts leads to slower growth in the number of elderly. At the same time, the projected increase in fertility during the first few decades, combined with rising immigration (excluding North America, Australia, Germany and Norway), contributes to a slower fall in the working-age population towards the end of the period in some countries (See Tables A.1 and A.2 in Annex).

Main common background macroeconomic assumptions

Taking these population projections as the starting point, the profile of GDP to 2050 was calculated in the following manner (See Table A.5 for specific country assumptions):

- Participation rates for the period to 2010 are based on ILO projections (ILO, 1997). For the subsequent period, the participation rates stay constant for men aged 20 to 54 (prime age) and 55 to 64 (older workers) as well as for all retirement-age individuals and all persons under the age of 20. Participation rates for women aged 20 to 54 and 55 to 64 rise progressively towards a ceiling at the end of the period equal to 5 percentage points below those of men in countries with widely subsidised child-care and 10 percentage points below elsewhere. Some countries deviate marginally from these rules because of

the expected impact of recent policies (e.g. higher retirement ages). However, with the exception of Austria,² these differences do not appear large enough to affect the results significantly.

- Unemployment rates converge to their structural levels (as defined by the OECD) in 2005, with unemployment rates held constant at the 2005 rate throughout the period to 2050, except for countries where existing labour-market reforms presupposed a further decline in structural unemployment over the period.³ The authorities in Belgium, France and Italy, and, to a lesser extent, the Czech Republic, Germany, Finland, Hungary and Poland built in this decline. The Spanish authorities allowed its unemployment rate to fall over the period to 4 per cent, well outside the agreed limits.
- Labour productivity growth (measured as GDP per worker) converges towards an annual rate of 1¼ per cent as from between 2020 and 2030. Some catch-up is allowed for initially low-productivity countries such as the Czech Republic, Hungary, Korea, Poland and Portugal. Assumptions for productivity growth were so high as to seriously compromise cross-country comparability in Portugal, and this country has been treated separately in this documentation. Average productivity growth rates are significantly lower in Canada and Norway because they start from low productivity growth rates. GDP was established by multiplying the number of employed by average productivity.

Where countries have short- to medium-term budget projections up to 2005, the ageing projections were run off these. Non-age-related expenditures and government revenues are kept constant as a share of GDP after this point, except to the degree that there are clearly identified effects arising from ageing or from background assumptions -- e.g. reduced spending on unemployment insurance as unemployment falls or higher tax revenues as a result of pensions paid from tax-sheltered savings in pension funds.

-
1. Sections 1 and 2 in the Annex provide further evidence on demographic and macroeconomic assumptions
 2. Instead of broad constancy in the participation rates for older male workers after 2010, the Austrian projections assume that they will rise by 33 percentage points, to 71 per cent, by the end of the period. This reflects the assumed impact of recent reforms to early-retirement policies.
 3. This adjustment was limited to one third of the structural unemployment levels in 2005.

The baseline projections for public expenditure

6. While much recent discussion has focused on old-age pension programmes, many other public expenditure programmes are affected by demographic shifts. These include programmes permitting early withdrawal from the labour market (long-term unemployment, disability, and early retirement programmes for labour market reasons), health care and long-term care for the frail elderly, family/child benefits and education. Unfortunately, not all countries provide projections for these other components.⁴ Comparisons across countries should be treated with caution because coverage of age-related spending is uneven across countries (Box 2). Nonetheless, based on information from countries that provided a wide range of spending items, spending components that are sensitive to the age structure of the population represent between 40 and 60 per cent of total public spending.

-
4. Thirteen countries provided information on programmes permitting early withdrawal from the labour market; eleven included child and family benefits and education and fourteen provided data for health and long-term care. Only eight countries provided data for all components of age-related spending, although, in some cases, this may reflect the fact that these programmes do not exist or that spending has been included under other components of age-related spending.

Box 2. Spending programmes covered in projections

Projections for individual countries cover a varying number of expenditure items.¹ Thus, while the following spending components are likely to be strongly affected by changes in population structure, information on all of these is available for relatively few countries:

- *Old-age pension spending*: This category includes all old-age pension spending as well as all early retirement pension spending which is an integral part of the public pension system (often implying a reduced pension). In addition, it includes survivors and social assistance or minimum pensions (all countries).
- *Programmes permitting early withdrawal from the labour market (“early-retirement” programmes)*: This covers programmes other than those included in old-age pension schemes permitting early withdrawal from the labour market. This includes programmes such as disability pensions, unemployment pensions, and some active labour market programmes targeted to workers aged 55+ to help them bridge the period between employment and receipt of an old-age pension.
- *Health care*: This includes all public health care expenditure for ambulatory and acute hospital care and for pharmaceuticals.
- *Long-term care*: These expenditures cover retirement homes and nursing care provided by the government as well as social services in the form of home help to keep the elderly as independent as possible.
- *Education*: This category includes all levels of education
- *Family and child allowances*.

Comparisons with the Social Expenditure Data file²

Comparisons between the historical data from the projections exercise for 1995 in country submissions with data from the Social Expenditure Data File (SOCX) at the OECD (Table 3) suggests that there may be important differences in the coverage of programmes. While some differences between the two data sets is likely because they draw on different data sources or follow different accounting rules (e.g. national account vs. budget basis or expenditures net of contributions), large differences between the two data sets help indicate expenditure items which may need to be treated with some caution.³

As regards old-age pension benefits (column 1), the current data-set seems to imply significant under-reporting for: Austria (public sector employee pensions are not included), Denmark, Korea, the Netherlands, Norway, the United Kingdom (data exclude the income-tested Minimum Income Guarantee and the pensions for public sector employees) and the United States (data exclude state and local government employee’s pensions). For these countries, the increase in pension spending over the next decades could therefore be underestimated.⁴ At the same time, the data for Sweden imply some over-reporting relative to the SOCX file, possibly because they include some disability spending with old age spending.

For nine countries (Austria, Canada, France, Germany, Italy, Japan, New Zealand, Spain and the United Kingdom) there is no information on programmes included in the category “early retirement” (column 2). For the remaining countries, comparisons with the SOCX file are somewhat difficult because programmes that have been included can vary from one country to another. Nonetheless, significant under-reporting seems to occur for Belgium and the Netherlands (where only old-age workers (55-64) are included) while the comparison indicates over-reporting for Denmark and Portugal.

No information is available concerning spending on health or long-term care for Austria, France, Germany, Italy, Poland, Portugal and Spain. Both components of health care are available for only 8 countries (Australia, the Czech Republic, Denmark, Finland, Japan, Korea, Sweden and the United States), although in Belgium, Canada and the Netherlands, long-term care is included in health care. For Norway and the United Kingdom projections of health spending are available but not of spending on long-term care. Compared with the SOCX file, the submissions suggest underestimation of health care costs in Belgium, Finland, Korea (which did not include social security health care

spending), Sweden and the United States. For the latter, only programmes on the elderly have been included (Medicare), Medicare is presented net of premiums and state and local programmes for health care for the elderly have been excluded.⁵ Finland included health care for the elderly in long-term care.

A comparison of data for family benefits suggests underestimation by between $\frac{3}{4}$ and $1\frac{1}{4}$ of a percentage point of GDP in Australia, New Zealand, Norway and the United Kingdom. Sweden overestimates these benefits by over 2 percentage points (they include child-care facilities for working mothers). A comparison of OECD data and country submissions for public education expenditure suggests that the Czech Republic, Denmark, New Zealand, Sweden and the United States under-report by more than one percentage point, while Australia, Canada and the United Kingdom over-report.

-
1. Ageing can also affect tax revenues, particularly where assets in tax-sheltered and funded pension arrangements are progressively paid out in pension benefits and become liable for tax. Only Canada, Denmark and the Netherlands provided information on this effect.
 2. Data for Poland and Hungary are not yet available in the SOCX data file.
 3. It should be noted, however, that a number of countries explored in depth the sources of the data entering the SOCX file but were unable to find the precise reasons for these differences.
 4. For the United States, the exclusion of state and local government employee pensions leads to an underestimation of total general government spending on old-age pension as well. But, as these pension schemes are fully funded, this underestimation has no fiscal implications.
 5. Expenditure in United States excludes non-elderly Medicaid, other State and local spending on health care and miscellaneous Federal programmes, such as care for war veterans. In the SOCX file, total public health care spending in the United States was around 6.3 per cent of GDP in 1995.

Old-age pension spending

Levels of spending around 2000

7. Old-age pension spending includes, in principle, all old-age pension spending, all early retirement pension spending which is an integral part of the public pension system, and survivors and minimum pensions. Currently, public old-age pension spending, as drawn from the national projection data, represents around $7\frac{1}{2}$ per cent of GDP. Comparisons with OECD sources (Box 2) suggest that the programme coverage in the projections may be less than full for Austria, Denmark, Korea, the Netherlands, Norway, the United Kingdom and the United States⁵ and, hence, for these countries, the spending projections reported here may involve some degree of underestimation. Little of the cross-country variation in pension spending in 2000 is explained by the degree of ageing as measured by the old-age dependency ratio. Rather, differences reflect wide variation in programme characteristics, including the degree of system maturity, and the degree to which pensions are financed through the public sector:

- In countries with programmes where benefits are largely paid through state-run or bi- or tri-partite earnings-related (ER) schemes, public retirement income is linked to past work and/or contribution histories, although flat-rate elements are nearly always present in the form of minimum pensions.⁶ Virtually all countries with well-developed and mature public-sector

5. See footnote 5 in Box 2.

6. In some of these countries, there are additional, compulsory complementary pension arrangements negotiated on an industrial sector or professional basis (*e.g.* blue-collar or white-collar), and often managed by the social partners (*e.g.* France), although this spending does not always appear in the government accounts.

earnings-related systems (Austria, Belgium, France, Germany, Italy, Poland, Spain and Sweden) tend to have above average pension spending, although the level of spending varies with the generosity of benefits and the age of retirement (Figure 3, Panel A). The US system provides low average benefits relative to previous earnings and has a higher retirement age compared with most of the European countries just referred to. In Korea and Norway, the pension system is still maturing;⁷

- In other countries, predominately flat rate (FR) schemes generally aim to provide a minimum basic income for the elderly irrespective of their work history. Spending under these systems is lower (Figure 3, Panel B), partly reflecting the fact that the basic pension component often serves as a safety net (and is therefore set at a lower level), with a larger share of income in retirement coming from private sources than for most countries with ER systems. For many countries with flat-rate schemes, the retirement age is 65 with little opportunity to receive pension benefits before this age. Such FR arrangements can be complemented by mandatory labour-market arrangements of a public or private nature and with various degrees of funding. The public component of these add-ons is, at present, generally less generous than in ER schemes.⁸

Old-age pension spending trends to 2050

8. Projections based on assumptions of unchanged policy -- though taking into account legislated but-not-yet implemented reforms -- suggest that old-age pension spending will rise on average by around 3 to 4 percentage points of GDP in the period to 2050 (Table 4, Panel B), but with considerable cross-country variation. Pension spending is projected to fall as a share of GDP over the period for Poland, where shifts are taking place towards private pension arrangements, as well as for the United Kingdom, and to remain broadly stable for Italy, partly reflecting recent reforms. In contrast, increases of more than 4 percentage points of GDP are projected for ten countries (including Portugal) and for seven among these, it will be 5 percentage points or more. Spending relative to GDP starts to rise quickly in the latter part of the current decade, but then slows from around 2035-40, with declines in a few countries.⁹ Indeed, significant differences between the change to the peak and the change over the entire period are projected by Austria, Belgium, Denmark, Italy, Japan, the Netherlands, Sweden and the United Kingdom.

9. To illustrate the forces driving the change in the share of spending in GDP over the period 2000-2050, Table 5 breaks it into four factors:¹⁰

- A dependency or population-ageing effect, reflecting changes in the ratio of those aged 55+ to the population aged 20 to 64.¹¹
- An employment effect, driven by changes in the ratio of the population aged 20 to 64 to employment.

7. While Korea is currently closer to a flat-rate system, spending increases are driven by a maturing earnings-related scheme introduced in 1988.

8. The maturing of the Canada and Quebec Pension Plans may lead to a greater role for ER schemes in the future.

9. Projected effects of reforms in a few countries (*e.g.* Italy and Sweden) contribute to this result.

10. See Annex, section 4, for details on the methodology followed

11. This takes into account the fact that a considerable number of older workers retire before 65.

- The benefit effect, related to changes in the average pension benefit relative to GDP per worker.
- An eligibility effect, corresponding to changes in the share of those receiving benefits in the 55+ age group.¹²

10. The results show the increase in spending associated with the change in each one of these components taken independently. The last two factors are measures of the changing generosity of pension systems.

11. While the results of such decompositions need to be treated with caution, they suggest that increased ageing/dependency is the key factor driving pension spending over the period (Table 5, third column). The average impact of ageing taken alone is around 5 percentage points of GDP. The ageing-induced increases are highest in a number of European countries which have fully developed and generous earnings-related pension schemes and/or rapid ageing (*e.g.* Austria, the Czech Republic, France, Germany, Italy, Poland, Portugal and Spain). Smaller increases are found in countries with limited ageing and low initial spending levels (*e.g.* Australia, Denmark, Hungary, the Netherlands, Norway, the United Kingdom and the United States).

12. Almost all country projections have increasing employment ratios as a result of assumed higher female participation rates, lower unemployment or increased average retirement ages. This boosts output and reduces the cost of pension systems taken as a share of GDP. This effect is stronger in countries with currently low female participation rates and/or high unemployment rates at the beginning of the period (especially Austria, Hungary, Italy, Japan, Korea, Poland as well as Spain, where unemployment is assumed to fall to the same levels as in the early 1970s).

13. As a general rule, the effects of the two aspects of system generosity reflect maturing pension systems, changes in behaviour and the impact of reforms (see Box A.1 in the annex for a list of recent major policy measures).¹³ Most countries project increases in the share of beneficiaries in the population aged 55 and over. Higher assumed employment of women and maturing pension systems should lead, by themselves, to an increase in the share of beneficiaries but be offset by the reforms undertaken in a significant number of countries aimed at directly increasing the effective age of retirement. But aside from Austria, Italy and Poland, these do not appear to be considered sufficient to reduce significantly the overall share of pensioners in the target population over the period.

14. In contrast, the projections indicate widespread declines in average benefits relative to productivity, making for a fall in expenditure averaging around 1½ percentage points of GDP. Once again, this reflects a range of offsetting factors. There have been important reforms aimed at reducing benefit rates: shifts from indexation of pensions on wages towards prices¹⁴ (Finland, France, Hungary, Italy, Japan,

12. For France, Japan, Sweden and the United Kingdom, it was necessary to assume that the number of beneficiaries equalled the non-active share of the population aged 55+. This approximation for the eligibility ratio leads to an overestimation of the number of beneficiaries. Correspondingly, with average benefits defined as total pension expenditure in any year divided by the number of beneficiaries, this procedure leads to an underestimation in the average benefit (calculated as the residual) for these countries. For Italy the number of pensions, rather than the number of pensioners, was used.

13. A recent and more detailed review of reforms can be found in OECD (2000).

14. This refers to earnings-related schemes. This change, in general, does not affect the individual's level of benefit at the time of retirement. However, over the retirement period, real benefits will grow by less than productivity. This will lead to a fall in total public pension spending during a transition period, as a progressively larger share of pensioners experience indexing only to prices through all of their retirement

Korea) or from pre-tax to after-tax wages (Austria and Germany), lengthening of the contribution period for a full pension (France) and lengthening of the reference period for calculating pensions (Belgium, the Czech Republic, Finland, France, Italy and Spain). These changes appear to have been large enough to offset a number of effects associated with the higher labour-market participation of women,¹⁵ lengthening contribution periods¹⁶ and composition effects as the baby boom generation enters retirement.¹⁷

15. Relative declines in benefits are particularly marked in a few countries. Italy will shift to a system where benefits are contribution-based, indexed to prices and actuarially adjusted to allow for increasing life expectancy. This is projected to lead to a reduction in average benefits equivalent to 5 to 6 percentage points of GDP. Similar reforms in Sweden are also expected to lead to substantial declines in average benefits. The sharp fall for Japan reflects legislation that requires benefits to be adjusted every five years to bring the pension system into balance. For France, the shift to indexing on prices, the lengthening of contribution periods and of the reference period for calculating pensions will progressively impact on spending. In addition to changing the indexing to net wages, German pensions only rose in line with prices in 2000 and 2001. From 2002, pension benefits will take into account lengthening in lifetimes. Declines in pension benefits in Poland reflect shifts to a private system. In the United Kingdom, the overall fall in pension spending reflects the assumed constancy in real terms of the flat-rate basic pension. Such policy reforms will lead to falls in average benefits relative to wages -- 20 per cent or more in some countries. These changes are sufficiently large as to require a build-up in private pension saving if income adequacy in retirement is to be maintained for all. Failing this, lower incomes and increased poverty among the elderly raise the risk of political pressure for a reversal of these policies, particularly as the elderly will make up a growing share of the electorate. This underlines the need for creating conditions that encourage private savings for retirement.

Programmes permitting early withdrawal from the labour market ("early retirement" programmes)

16. In addition to old-age pensions, most countries have programmes that provide income support for those of working age -- for example, disability pensions, long-term unemployment benefits and early-retirement arrangements for labour-market reasons. In a number of countries, expenditure on these programmes is high, and they are often seen as an integral part of overall pension arrangements (*e.g.* Denmark, Finland, Norway). These programmes can be affected by ageing, for example *via* larger numbers of older workers with their higher probabilities of becoming disabled. They are also sensitive to labour-market developments as these programmes have often been used to provide income support for

period. Estimated average benefits, calculated over all retirees, fall during the transition period, though eventually pensions increase at the same (constant) rate of productivity growth.

15. The assumed increase in women's participation should also lead to a progressive decline in the number of individuals on widows and survivor benefits and an increase in regular pension benefits which are generally higher in ER schemes. But outcomes will depend on hours worked and the development of male-female wage differentials.
16. Where pensions are linked to the number of years of work or contribution, average benefits will increase as pension systems mature. Many of the currently retired have short contribution histories and receive minimum pensions. Longer contribution periods, particularly for women, will be reflected in higher average pensions.
17. In the case of an earnings-related schemes with pensions indexed to prices, those entering retirement have higher pensions than those at the end of their lifetimes. The baby boom cohorts are larger than the current cohorts in retirement. As a consequence, they will weigh more heavily in the total number of pensioners when they enter retirement. Since they have higher benefits than the average when they retire, the average benefit (calculated over all pensioners) will tend to rise. This process will be reversed towards the end of the period as these cohorts are replaced by the smaller cohorts that follow them.

older workers who have difficulties finding employment, or remaining in employment, until retirement age is reached. Such programmes have contributed in many countries to the marked fall in the participation rates of older male workers over the past several decades. Many countries have introduced reforms to tighten access to these programmes and to limit benefits.

17. While the coverage varies across countries, these programmes represent around 1½ percentage points of GDP in the countries providing data, although considerably more in Denmark, Finland, Norway and Portugal (Table 4, Panel C). Despite the increasing average age of the working population over the period, countries providing these data generally project broad stability or marginal declines in expenditures, possibly reflecting programme reforms already undertaken and declining unemployment. Significant increases over the full 50-year period are projected only by Norway.

Health care

18. Public health care and long-term care spending varies considerably across countries, even among those at the same level of *per capita* income, reflecting a wide range of historical and institutional factors, including the fact that the share of total spending which is paid for directly by households (including via private insurance schemes) can vary substantially. Reported public health- and long-term care spending averages around 6 per cent of GDP in 2000 (Table 4, Panel D), although some differences in coverage mean that these results may not be rigorously comparable across countries.

19. Projections of health care spending (including costs of care for the frail elderly) are considerably more uncertain than for pension expenditure. Pension legislation provides a framework for estimating future benefits. No equivalent set of rules is available for projecting the demand for and supply of health care. Further, there is a great deal of uncertainty as to which demographic features are most important for driving health care spending -- in particular, whether it is the fact of having a higher share of the population that are relatively old or whether it is having a higher share in the final years of their lives. Partly as a result, the method of projecting health care spending can vary considerably. For most countries, projections are broadly based on projected *per capita* health care expenditures by age group (which rise with age) multiplied by the number of people in each age group. These are then allowed to increase in line with selected macroeconomic variables. However, the projections for the Netherlands allow for the fact that a large share of total lifetime health care costs occurs in the last year or two of life. Non-age-related factors (such as higher income and technology change) have been taken into account to varying degrees. (The Annex, section 5, provides a fuller discussion of the method used by individual countries).

20. The average increase over the 2000-2050 period for the 14 countries where this information is available is 3 to 3½ percentage points of GDP. But for five countries (Australia, Canada, the Netherlands, New Zealand and the United States) increases of 4 percentage points or more are projected. Many factors contribute to the large cross-country differences. Slow ageing is partly responsible for the smaller increases in spending in Denmark, Sweden and the United Kingdom. However, differences in individual country estimates of the health care costs *per capita* for the elderly relatively to younger age groups also appear to be important additional factors as well as assumptions regarding how per-capita health care costs rise over time.

Child-related programmes

21. Spending on education and family/child benefits taken together average 6¼ per cent of GDP for the countries presenting data (Table 4, Panel E). With modest falls in youth dependency ratios expected over the projection period, these two programmes are projected to offset spending increases elsewhere to the extent of around 1 percentage point of GDP on average over the projection period. Falls in spending as

a share of GDP are foreseen in all countries except Denmark, the Netherlands and Norway. There is no certainty that all of these potential economies will be reaped. In practice, it has been difficult to make cuts in these areas and there may well be further pressures arising from longer periods of education for the young, increased training for older workers and more demand for publicly-subsidised child care as the share of women working increases.

Total government spending, taxes and the primary deficit

22. The projections point to a generalised deterioration in the public sector primary financial balance over the projection period reflecting:

- The increase in old-age pension spending.
- Changes to other age-related spending in countries providing such information.
- Changes to non-age-related spending and to revenues.

23. As regards the last tier, it was agreed that, with some exceptions, the projections of revenues and non-age-related spending would be based on assumptions of unchanged shares in GDP over the projection period. However, some countries took into account changes to spending and/or revenues in the period to 2005 as a result of policies already enacted. Other changes in non-age-related spending can also be expected as a result of the macroeconomic assumptions, for example lower levels of spending on unemployment benefits. Moreover, Canada, Denmark and the Netherlands with large tax-sheltered private-sector pension schemes include increases in revenues from taxes paid on the associated pensions.

24. Bearing in mind these considerations, the projections point to a decline in the primary surplus or increase in the deficit of 6 to 7 percentage points of GDP, over the period 2000-2050 for countries projecting more spending categories than just old-age pensions (Table 6, Panel A). Excluding the effects of other age-related spending (column 4), the change in the deficit related to old-age pension spending across the same set of countries amounts to around 4½ percentage points of GDP, but with wide country variation. In the three countries providing projections for old-age pension spending only, there is a large reduction in the surplus for Spain, a more modest fall for Germany (where, like the Netherlands, the rise in pensions is partly offset by a substantial rise in revenues) and a limited increase for Italy (Table 6, Panel B).

25. The likely deterioration in the primary balance is projected to be substantially larger than the impact of old-age pension spending alone in the countries that project only the latter. This can be seen by examining the projections for countries providing estimates of age-related budget items other than pensions (Table 6, Panel A). For those countries, the additional deterioration in the primary balance due to non-pension age-related spending is 2½ percentage points of GDP (Table 6, Panel A, third and fourth columns).

Box 3. Ageing in a “stylised” country: the impact of deficits on debt

The change in debt associated with the rise in age-related spending is a better indicator for the overall fiscal impact of ageing than the change in the primary balance. However, debt profiles for individual countries are sensitive to assumptions and to the situation at the start of the projection period, making cross-country comparisons difficult to interpret. To provide some idea of likely magnitudes, this box traces developments of the impact of ageing on debt and of policy measures needed to offset this impact, using a “stylised” OECD country (one which has the features of the median OECD country as regards individual parameters) as an example. In 2000, pension spending of the “stylised” country represents around 8 per cent of GDP, the primary surplus 2.5 per cent and net debt 55 per cent of GDP. The profile of age-related spending over the 50-year period is constructed by using median values for the share of pensioners in the population, average relative pension benefits, health care spending and other age-related spending. This leads to a projected increase in age-related spending of around 6 percentage points of GDP.¹ Assuming other government spending and revenues remain constant as a share of GDP, the change in age-related spending is fully reflected in the overall primary balance.

The impact of ageing on primary balances and debt (Table 7, Panel A)

Assuming 1.9 per cent annual real GDP growth and a real interest rate of 4 per cent, debt would increase over the period to 2050 by almost 100 percentage points of GDP. This baseline increase can be broken down into two parts:

- A rise in net debt of almost 200 percentage points of GDP from the increase in age-related spending alone, *i.e.* abstracting from the initial levels of debt and the primary surplus.
- A decline in debt or increase in assets of around 115 percentage points of GDP as a result of the initial primary surplus (the non-ageing related component of which is assumed unchanged through the period).²

Thus, for the “stylised” country, about half of the impact of age-related spending on debt can be offset by sustaining the initial “non-age-related” primary surplus over the entire period. In contrast, if a country had an initial primary deficit of 1 per cent of GDP, sustained throughout (compared to a surplus of 2.5 per cent in the baseline) its total debt would increase by more than 400 percentage points of GDP by the end of the period. It is also important to sustain initial surpluses over time. If, for example, non-age-related budget items changed so as to reduce the “non-ageing” surplus to zero after 10 years, the debt would be almost triple the baseline value by the end of the period.

The following sensitivity tests provide some indication of the impact of different assumptions and circumstances in individual countries (changes are indicated relative to baseline):

- A sustained increase in the primary surplus of 1 percentage point of GDP over the baseline will lead to a broadly unchanged debt to GDP ratio at the end of the period.
- If age-related spending rose somewhat less rapidly, ending at 1 percentage point of GDP lower by the end of the period relative to baseline, the increase in net debt would be around 35 percentage points less.
- If debt at the beginning of the period were 10 percentage points lower, the rise in net debt would be around 20 percentage points of GDP less.
- If the interest rate were 1 percentage point lower through the period, the debt increase would be around 35 percentage points of GDP lower at the end of the period.

Policy measures to limit the impact of ageing (Table 7, Panel B)

Two stylised reforms of pension systems are considered in Table 7, Panel B: a reduction in average pension benefits and a fall in the number of pension beneficiaries (reflecting delayed retirement) that would be required to keep debt in 2050 at the same level in terms of GDP as in 2000.³ The results suggest that the required per cent fall in the number of pensioners would be lower than for average pensions, reflecting the feedback effects of fewer pensioners on GDP (through higher employment), as well as increased tax revenues.⁴

Delaying the implementation of reforms by 10 years (to 2015) would increase the required adjustment in either the number of pension beneficiaries or average benefits by around one-fourth, while delaying them by 20 years would require an increase of around three-quarters.

Alternatively, countries could offset higher age-related spending through a sustained increase in the primary surplus (from the baseline value of 2.5 per cent) at the beginning of the period. In this case, the increase in the primary surplus needed to keep debt unchanged at the 2000 level of 55 per cent of GDP would be 1.1 percentage points of GDP. To eliminate debt entirely by 2050, the primary surplus would have to increase by 1.8 percentage points of GDP.

-
1. This is broadly equivalent to the sum of the averages of each component of age-related spending in Panels B to E of Table 44.
 2. The change in the primary surplus over the period 2000 to 2050 is the sum of the change due to age-related spending and the change arising from the net effect of the development of non-age-related spending and of revenues. Since both non-age-related spending and revenues are held constant as a share of GDP in these simulations, the second component remains unchanged after 2005.
 3. The reduction in both the number of pensioners and average pension benefits is implemented in 2005 and sustained over the period until 2050.
 4. This assumes that people postponing retirement will remain employed. For further details see Annex, section 7.

26. The overall impact on the fiscal situation of these developments will depend on the cumulated change in the primary balance over the projection period, coupled with the associated change in debt-interest payments. The outcome in terms of debt as a share of GDP is highly sensitive to the initial levels of debt and primary balance, the change in the primary balance through the period and the assumed interest rate (relative to GDP growth). As is shown in Box 3—which examines the relation between deficits and debt for a “stylised” country -- small changes can lead to substantial differences by the end of the period. As a consequence, simulations of debt outcomes for individual countries are highly uncertain. Nonetheless, the results shown in Box 3 suggest, first, that countries will be in a better position to confront ageing pressures if their primary surpluses are sufficiently high for them to reduce their net-debt positions rapidly in the period before dependency ratios begin to rise sharply. This seems to be the case, for example, in Belgium and Canada (which each have high debt levels currently). Thus, measures to move the primary balance into surplus are desirable, on these grounds, in the near future, and this is all the more the case where countries already have high levels of debt or are in deficit. However, it is important not only to achieve appropriate levels of the primary surplus but also to maintain them over the long-term. Second, for the “stylised” country the accumulated impact on public debt of ageing is large, approximately 200 percentage points of GDP.

Sensitivity tests

27. For estimates over such a long time frame, it is particularly important to have information on the robustness and the degree of uncertainty surrounding the projections. Sensitivity analysis has been performed for seven of the most important assumptions underlying the projections (Box 4) for 13 countries at the level of pension and total age-related spending (Table A13). Some factors which may help explain cross-country differences are described in the Annex, section 6.

Box 4. Assumptions subject to sensitivity analysis

Demographic assumptions

1. *Higher fertility rate.* Fertility rates for all age groups are assumed to rise by 15 per cent relative to the baseline until 2029 and remain constant at the higher level thereafter.
2. *Longer life expectancy.* Mortality rates are assumed to fall by 30 per cent and 20 per cent respectively for males and females for all age groups by 2050. This corresponds broadly to an extra 3 ¾ years of life expectancy at birth for males and 2 years for females by 2050.
3. *Higher migration flows.* Net migration in numbers of persons gradually increases from year 2000 to 50 per cent above the baseline level in 2010, remaining constant over the rest of the period.¹

Macroeconomic assumptions

4. *Lower participation rates for older workers.* Participation rates of older workers (55 to 64) are set 5 percentage points lower than assumed in the baseline by 2050.
5. *Lower female participation rates.* Total female participation rates (20-54) are 5 percentage points lower than assumed in the baseline projection by 2050.
6. *Lower unemployment rate.* The structural unemployment rate falls by the end of the period to levels experienced in the 1960s (unemployment rates of 3 to 5 per cent).¹
7. *Lower productivity gains.* Productivity growth is 0.5 percentage points per annum lower than the baseline starting in 2005 and ending in 2050.

1. The size of the shocks in the sensitivity tests for immigration and unemployment differ across countries. Rough adjustments to the results presented by countries have been made to improve cross-country comparability. See Annex and Table A.13.

28. Taken individually, the sensitivity shocks do not appear to alter significantly the broad message of the baseline projections (Table 8). The simulation of increased longevity -- which has been set, like the simulations of increased fertility, to have a two-thirds probability of occurring on the basis of past projection errors¹⁸ -- indicates that old-age-pension spending could be, on average, about one percentage point of GDP higher, and total age-related spending some 1½ percentage points higher. The probability that the changes assumed in the other sensitivity tests might occur is difficult to assess. But for the magnitudes chosen, the impact is not large. The results for productivity suggest that very substantial

18. Eurostat has calculated, for each country, a probability distribution of errors on the basis of previous projections for both mortality and fertility. Taking this as a starting point, it then established changes in these two variables that were at the limit of a two-thirds confidence interval of this probability distribution. To increase the comparability across countries, a mean value for the limits of the confidence interval was established across countries and this common value was then applied to all OECD countries. These ensured similar movements in fertility and mortality across countries in the sensitivity tests shown in Table 7 and these changes are broadly consistent with a two-thirds chance of occurring.

increases in economic growth (through higher productivity) would be necessary to significantly offset the increased costs of ageing.¹⁹ Projected tax receipts varied little in the various sensitivity tests.

What are the policy options?

29. In sum, on the basis of present policies, age-related spending is likely to increase on average by 6 to 7 percentage points of GDP and significantly more in some cases. Spending projections could be still higher than those presented here if the extent of population ageing turns out to be underestimated (Schieber and Hewitt, 2000). These impacts have to be evaluated in the light of the improvement in underlying budget positions over the past half decade. Cyclically adjusted primary balances have improved in most OECD countries, in many cases moving into surplus. Debt is falling as a result. If the non-age-related components of these surpluses can be sustained over time, a substantial part of the projected increase in age-related spending can be absorbed, thereby reducing the extent of fiscal strains. Nonetheless, there is no reason for complacency. First, higher non-ageing primary surpluses than currently registered, sustained over half a century, would be required to prevent debt-to-GDP ratios rising above current levels -- which are already considered to be too high in many countries. Second, a few countries are still in primary deficit, and reforms in these countries are all the more urgent if rapid accumulation of debt is to be avoided as ageing accelerates. Third, large primary surpluses have been achieved, in most cases, by increases in tax pressure from an already high level, with accompanying distorting effects on markets, potentially leading to slower growth. Fourth, a large stock of public debt implies a high degree of vulnerability to changes in interest rates, particularly when a large share of the debt is short term. Fifth, most governments experience pressure to “spend” surpluses where they occur -- either through higher expenditure or lower taxes -- implying that these surpluses may not be easy to sustain. Finally, in most countries, pension spending already accounts for a large share of social spending and this will progressively increase. This, in turn, will limit budget flexibility and the resources available for other spending programmes.

30. As regards pensions, reforms have already been introduced in many countries. But, even if the overall fiscal situation appears better than several years ago, further reforms to age-related programmes are still needed in many countries. While a comprehensive range of policies will be required to limit the rise in spending (OECD, 1998), it is of interest to consider the relative effects of key individual policies taken in isolation, and, in particular: a reduction in average benefits of old-age pensions; a reduction in the number of beneficiaries of old-age pensions reflecting delayed retirement; and, an increase in the primary surplus that is sustained throughout the period.

31. On the basis of a simplified methodology, and using the “stylised” country as the model, the OECD Secretariat has calculated the required change in average benefits and in the number of pension beneficiaries in 2005 (and sustained throughout the period) to keep the debt-to-GDP ratio constant at around 55 per cent of GDP by 2050) (Table 7, Panel B).²⁰ The results -- which should only be considered as approximate -- suggest that the required reduction in the number of beneficiaries could be close to 8 per cent -- corresponding to a rise in the effective age of retirement of about one year -- while the required fall in average benefits might have to be more than double that, at around 17 per cent. The larger required action on pension benefits as opposed to pensioners reflects the feedback effects of fewer pensioners on higher employment and GDP, as well as the effect on tax revenues. In reality, however, cutbacks in pension generosity might well induce people to work longer, while later retirement in some countries

19. Higher productivity growth increases both GDP growth and pension spending in the case of earnings-related-pension schemes. The size of the impact of the change in productivity growth will be larger in flat-rate schemes, but only if the gap between wages and benefits is allowed to widen.

20. It was assumed that the reduced number of beneficiaries was balanced by an equivalent increase in employment -- *i.e.* there was no increase in the share of the unemployed or of the inactive.

automatically leads to higher pensions, suggesting that the separation of these two effects may not be so neat or the differences so marked.

32. Alternatively, countries could offset the impact of ageing on the deficit by running high enough primary surpluses through the remainder of the period. The simulations for the “stylised” country suggest, for example, that the age-related increase in spending, taken by itself, could be fully offset by a primary surplus of 3½ percentage point of GDP and sustained through the period (Table 7, Panel B). This is because the non-age-related surplus, assumed unchanged, helps counteract the age-related fiscal pressures as they emerge.

33. These averages embodied in the “typical” country case mask important differences across countries reflecting the size of spending increases, their timing and the initial fiscal position. As discussed in the Annex, countries where spending increases are larger will need a larger sustained increase in the primary surplus. However, the timing is also important: countries where age-related spending begins to increase earlier will need a higher initial primary surplus to compensate if debt is to remain unchanged at the end of the period. Finally, countries with a net asset or low public-debt position at the beginning of the period will require smaller adjustments as debt is, in most circumstances, already being reduced (or assets built up) at a sustained rate.

34. There is a narrow window of opportunity before dependency ratios begin to rise rapidly. Countries can profit from this period by improving the overall fiscal situation and announcing reforms, especially as policies have to be phased in progressively so as to allow households the time to adjust. Clearly, if policies are implemented with a considerable delay, stronger measures will be required to achieve the same fiscal outcomes by mid century. For example, the required reductions in pension benefits and the number of beneficiaries to offset the impact of ageing on debt have been re-estimated assuming that reforms were implemented 10 years later (*i.e.* in 2015 rather than 2005). The results indicate that, to achieve the same objective in terms of debt reduction, the reforms would need to be one-quarter larger than if implemented immediately and a delay of 20 years would increase this amount to three-quarters (Table 7, Panel B).

35. In choosing which reforms to introduce, countries will also focus on the impact on incomes of the elderly. Sharp falls in average benefits may mean a widening gap between wage earners and incomes of the retired and increased poverty among the elderly. Where these changes are large, political pressure may build up to reverse these policies. To palliate such effects on incomes and increase the political sustainability of reforms, there may be a need for flanking policies that provide alternative sources of income in retirement -- for example funded private pension (or savings) arrangements, possibly of a mandatory nature, or scope for maintaining earnings. In this context, it is notable that policies that delay retirement allow fiscal goals to be achieved with less need to reduce retirement incomes, underlining once again the desirability of measures that encourage people to work longer in order to qualify for a full public pension.

36. In addressing long-term fiscal issues, countries need to consider a wider range of policy instruments than those just discussed and a number of these have been laid out in *Maintaining Prosperity in an Ageing Society* (OECD, 1998) and in the *OECD Jobs Strategy*, (OECD, 1999).

- Policies permitting withdrawal of older workers from the labour market will have to be monitored closely. Even though all reporting countries except Norway project broad stability or declines in spending on these programmes as a share of GDP, the rising share of older workers in the working-age population may still put upward pressure on expenditure.

- The impact of later retirement, higher participation rates of older workers and immigration depends on whether the individuals concerned find employment. Their employment opportunities will be promoted by reforms to reduce structural unemployment and encourage rapid employment growth, as laid out in the *OECD Jobs Strategy*.

37. Closer attention to ways of controlling health- and long-term care costs is also desirable. Demand for publicly provided services will climb with the number of the elderly and of the very old. At the same time, increasing participation rates of the working-age population and smaller family sizes are likely to limit the scope for families to care for the elderly in the future. In this context, it is essential to increase both the efficiency and the effectiveness of the health care and long-term care system. At the level of health care, budgetary caps remain the main method of spending control but such policies can lead to rationing and reduced quality of care. Introducing needed micro-economic reforms aimed at improving the efficiency and the effectiveness of health care systems has proved much more difficult. Over the near future, policy-makers need to find ways of limiting the demand for and supply of those aspects of health care that are unnecessary, strengthening the effectiveness of delivery, and improving the match between health care needs and the supply of services. Over the longer term, health care expenditure will be driven -- in addition to increased ageing -- by incentives embedded in health care systems, the diffusion of technology and relative prices for medical services, suggesting that a wide range of policies will need to be considered if the long-term costs of health care are to be kept under control.

38. Limiting the need for state-financed institutional care for the frail elderly will help contain costs of care significantly. In any case, ensuring that individuals are able to remain independent and to care for themselves for as long as possible is an important policy goal in its own right. Since the demand for services for the frail elderly is closely linked to disability, policies of a preventive nature may be a cost-effective response in certain cases (Jacobzone *et al.*, 2000). In addition, an appropriate level and mix of supply, including significant support to remain at home, should help limit costs by ensuring that the level of care is in line with the degree of disability and minimises overall costs -- *e.g.* less need to keep elderly requiring long-term-term nursing care in higher-cost acute-care institutions.

United States	1.4	0.7	4.2	-0.6	-0.2	1.6

Note: A positive sign indicates that countries report lower spending than on that reported in their OECD data files (e.g. the SOCX data). Where SOCX data were not available countries were not included (e.g. Hungary, Poland).

1. The data file used is the OECD Social Expenditure Data File (2000) unless stated otherwise

2. Old-age cash benefits plus survivors in SOCX minus old-age pension spending in country submissions

3. Disability cash benefits and unemployment pensions in SOCX minus programmes permitting early withdrawal from the labour market (disability pensions, unemployment pensions, and active labour market programmes targeted to workers 55+ to help them to bridge the period between employment and the entitlement to an old age pension) in country submissions. The latter is mainly disability

4. Total health care in SOCX (excluding services for the elderly) minus total health care in country submissions

5. Services for the elderly and disabled in SOCX minus care for the elderly in country submissions

6. Family cash benefits in the SOCX data file minus child and family benefits in country submissions

7. Direct public expenditure for educational institutions for all levels of education combined in 1995 (OECD, *Education at a Glance*, 1998) minus education expenditure in countries' submissions

8. Long-term care is included in total health care

Source: OECD

a) The peak values are in 2050 except for Denmark (2030), Sweden and the United Kingdom (2035), and Belgium, Norway, the Netherlands and Korea (2040).

b) The peak values are in 2050 except for Japan (2015), the United Kingdom and Italy (2030), the United States, Sweden, Austria, Denmark and France (2035), and the Netherlands, Norway and Belgium (2040).

c) The peak values are in 2050 except for Belgium and Denmark (2025), Finland (2010), the Netherlands (2020), Poland (2035) and Sweden (2005). For Czech Republic the highest level is in 2000.

d) The peak values are in 2050 except for Denmark and Korea (2035), Norway and the United Kingdom (2040).

e) 0.0 indicates the highest level is in 2000. The peak values are in 2035 for Denmark and in 2040 for Norway and the Netherlands.

f) Total pension spending includes other age-related spending which does not fall within the definition in Panels B to E. This represents 0.9 per cent of GDP in 2000 and rises by 0.1 percentage point in the period to 2050.

g) Total includes other age-related spending not classifiable under the other headings. This represents 6.3 per cent of GDP in 2000 and increases by 0.2 percentage points from 2000 to 2050.

h) For France, the latest available year is 2040.

i) Total includes old-age pension spending and "early retirement" programmes only.

j) "Early retirement" programmes only include spending on persons 55+.

k) OECD average excludes countries where information is not available and Portugal which is less comparable than other countries.

l) Portugal provided an estimate for total age-related spending but did not provide expenditure for all of the spending components.

Source : OECD.

Table 5. **Decomposition of changes in old-age pension spending : 2000-2050**^a

<i>Portugal</i>	8.0	4.5	6.1	-1.0	-2.7	1.1

a) See Annex for methodology and detailed information on the time profile. Columns do not add up because linear approximations are used.

b) The associated percent declines in average benefits relative to average productivity over the period 2000 to 2050 is particularly important in the following countries: Belgium (-16%), Denmark (-11%), France (-21%), Germany (-20%), Italy (-30%), Japan (-38%), Poland (-51%), Sweden (-22%) and the United Kingdom (-47%). All other countries are under 10 per cent except Norway where the average benefit is projected to rise by 53.6 per cent.

c) For France, data are available for 2040.

d) For these countries information on the number of pension recipients and average pensions was not available. These variables were estimated by the OECD Secretariat except for Italy, where data refer to the number of pensions and not the number of pensioner

e) Average excludes countries where national information is not available and Portugal which is less comparable than other countries.

.. Refers to unavailable data.

a) Changes in the primary balance holding age-related spending other than pensions constant.

b) For Poland, total includes old-age spending and "early retirement" spending only.

c) Projections for revenues do not include the recent tax reduction proposals of the United States Administration.

Source: OECD.

Table 7. The Impact of Ageing in a "Stylised" Country, 2000-2050 ^a

Panel A. Changes in primary balances and net debt for a "stylised" country
(difference between 2000 and 2050 in percentage points of GDP)

	Change in:		Difference relative to baseline
	Primary balance	Debt	
<i>Baseline</i>			
Impact of all age-related spending on the "stylised" country	-6.1	-96	
-- Impact abstracting from initial debt and primary surpluses ^b	-6.1	-210	
-- Impact of initial and sustained primary surpluses ^c		115	
Impact of pension spending alone ^d	-4.2	-74	22
<i>Policy simulations</i>			
Sustained primary deficit of 1 per cent of GDP ^e	-6.1	-435	-340
Primary surpluses disappear after 10 years	-8.6	-274	-178
<i>Sensitivity test</i>			
Sustained increase in the primary surplus of 1 percentage point of GDP ^f	-6.1	-1	97
Age-related spending is 1 percentage point lower in 2050	-5.1	-62	34
Initial debt is 10 percentage points lower	-6.1	-75	21
Real interest rates are one percentage point lower	-6.1	-61	35

Panel B. Policy measures to keep debt constant as a share of GDP at the end of the period

	Year policy measure takes effect:		
	2005 ^g	2015 ^g	2025 ^g
Reduction in the number of pension beneficiaries (per cent)	7.7	9.5	12.3
Reduction in average pension benefits (per cent)	17.3	21.3	29.9
Increase in the primary surplus needed to keep debt constant at the level in 2000 ^h	1.1		
<i>Memorandum item:</i>			
Increase in the primary surplus needed to eliminate all debt by 2050 ^h	1.8		

a) The "stylised" country has pension spending equal to 8 per cent of GDP, a primary surplus of 2.5 per cent and net debt to 55 per cent of GDP. This country experiences an ageing-related shock measured by the median value in country submissions for the number of pensioners, average pensions, health-care spending and other age-related spending over the period.

b) Initial debt and primary balances, excluding the effects of ageing, are set to zero.

c) Assumes that age-related spending increases in line with GDP.

d) Assumes that other age-related spending increases in line with GDP.

e) The primary deficit is assumed to be 1 per cent of GDP initially (compared to a surplus of 2.5 per cent in the baseline). The deficit is assumed to remain constant over the period, excluding the effect of ageing. The impact of ageing is then introduced in this new baseline.

f) Increase throughout the period from 2000 excluding the effect of ageing. The impact of ageing is then introduced in this new baseline.

g) The reduction is fully implemented in the corresponding year and sustained through the period.

h) The surpluses are sustained throughout the period.

Source: OECD.

Table 8. Average impact of sensitivity tests on total age-related spending: 2000-2050 ^a

(Percentage points of GDP)

	Old-age pensions	Total age-related spending		Old-age pensions	Total age-related spending
Increased longevity (+3 years for males and +2 years for females relative to baseline)	1.0	1.4	Fall in unemployment rates (decline to levels experienced in late 1960s)	-0.3 ^b	-0.5 ^b
Higher fertility (+15% relative to baseline)	-0.7	-0.8	Lower older worker participation rates (5 percentage points lower by 2050 relative to baseline)	0.3	0.5
Higher migration (+50% by end of period relative to baseline)	-0.5	-0.7	Lower female participation rates (5 percentage points lower in 2050 relative to baseline)	0.3	0.5
Fall in labour productivity growth (fall in growth rate by 1/2 point relative to baseline)	0.5	0.6 ^c			

a) Results are defined relative to baseline at the end of the period. Results are averaged over countries providing data. For country coverage see Table A.13. France, Germany, Italy and Spain are excluded from the results for total age-related spending.

b) This indicates the impact relative to baseline. However, the baseline forecasts included some decline in unemployment rates particularly for Belgium, Italy, France and Spain, such that the impact of the total fall in unemployment over the period would be larger than reported here.

c) Excluding the Czech Republic and the United States because projections of spending on health and long-term care and education are insensitive to the change in productivity growth in these two countries, i.e. lower productivity growth does not lead to a fall in wage growth relative to baseline in these two countries.

ANNEX: SUPPORTING MATERIAL

1. Population projections

39. The total population is projected to decline in absolute terms in ten of the countries under consideration (Austria, Belgium, Czech Republic, Finland, Germany, Hungary, Italy, Japan, Poland and Spain) (Table A.1). The old-age dependency ratio (defined as the ratio of the population age 65 and over to the working-age population aged 20-64) rises in all countries but the speed and timing differ across countries. A decomposition of the old-age dependency ratio indicates a continuing rapid fall in the working-age population due to low fertility rates, combined with a continued increase in the number of the elderly but in many countries it will reach a peak between 2030-2035 (Table A.2). This mainly reflects an absolute fall in the number of the elderly as the baby boom generation passes away and, to some extent, a more modest decline in the working age population, as result of immigration and the recovery in fertility rates in some countries (See Box 1 in the main text). The youth dependency ratio (defined as the ratio of the population under 20 to the population aged 20 to 64) falls in all countries except Italy, the Netherlands and Portugal. Particularly large declines are projected for Canada, Korea, New Zealand and Poland.

40. These demographic developments are also very sensitive to underlying demographic assumptions and, in particular, to longevity. Alternative projections used in the sensitivity analysis (see below), in which the assumption for longevity is calibrated on an increase in average lifetimes at birth of 3¾ years for males and 2 years for females on top of those in the baseline (Table 1 in the main text), result in an old-age dependency ratio 6 percentage points higher than in the baseline projections at the end of the period. (Table A.3 and Table A.4).²¹

2. Assumptions underlying the macroeconomic projections

41. The values chosen by countries for unemployment and participation rates, on the basis of the assumptions in Box 1 of the main text, are shown in Table A.5. This indicates wide variation in the change in participation rates across countries, with larger increases in participation rates for women in countries with low participation rates at the beginning of the period. While participation rates for males aged 25 to 54 were agreed to be kept constant, Australia, Austria, Italy, Poland, Spain and Sweden assumed increasing rates. Since the increases of female participation rates were set in terms of the male rates, this has knock-on effects on female participation rates as well. Upward adjustment in participation rates in the 54-65 age group occurs in a few countries, reflecting the assumed impact of reforms to pension systems (Australia, Austria, Belgium, the Czech Republic, Germany, Italy, the Netherlands and Poland). The increase for Austria is 33 percentage points well above the other countries. Some countries reduced unemployment rates to below the structural rate in 2000 by the end of the period, reflecting the assumed impact of the labour market reforms (Belgium, France, and Italy, and to a lesser extent, the Czech Republic, Germany, Finland, Hungary and Poland). The decline in the unemployment rates for Spain was outside the agreed guidelines under this exercise. The sensitivity analysis reported below provides some indication of the importance that this might have.

20. These assumptions for increased longevity, which were estimated by Eurostat, were set so as to broadly represent having a 2/3 probability of occurring. The probability distribution was based on previous errors in population projections in EU countries. A similar approach was used for fertility. Thus, the results of these simulations are broadly comparable.

3. Profile of age-related spending over time

42. The profiles of age-related spending from 1995 to 2050 are shown in Tables A.6 to A.12 for the six components of age-related spending included here (old-age pension, “early retirement” pensions, health care, long-term care, family and child benefits and education).

4. Decomposition of the change in old-age-pension spending.

43. Table 4 in the main text uses a simple decomposition to isolate the impact of four ratios:

- A dependency ratio (ODR): those aged 55 and over as a share of the population aged 20 to 54;²²
- The employment ratio (EMP): the inverse of the ratio of employment to the working-age population (20-64).
- The benefit ratio (BEN): the average benefit relative to GDP per worker;
- The eligibility ratio (ELIG): the share of individuals 55 and over receiving benefits;

These were estimated using the following formulae:

$$\frac{\text{Pension spending}}{\text{GDP}} = \left(\frac{\text{Number of pension recipients}}{\text{Employment}} \right) * \left(\frac{\text{Average pension benefit}}{\text{Average productivity}} \right)$$

where the ratio of pension recipients to employment can be decomposed into the ratio of those aged 55 or older to the working age population (ODR), the inverse of the employment ratio (EMP) and the proportion of those aged 55 or older who are entitled to a pension (ELIG).

$$\frac{\text{Pens}}{\text{GDP}} = \frac{\text{Pop}(55+)}{\text{Pop}(20-64)} * \frac{\text{Pop}(20-64)}{\text{Empl}} * \frac{\text{Rec}}{\text{Pop}(55+)} * \frac{\text{AvBen}}{\text{AvPdy}} = \text{ODR} * \text{EMP} * \text{ELIG} * \text{BEN} \quad (1)$$

44. The linear decomposition of the change in levels in the ratio of public pension spending as a share of GDP can be expressed as:

$$\begin{aligned} \Delta_{t,t+i} \left(\frac{\text{Pens}}{\text{GDP}} \right) &= \left(\frac{\text{Pens}}{\text{GDP}} \right)_t \cdot \dot{g}_i \left(\frac{\text{Pens}}{\text{GDP}} \right) \\ \Delta_{t,t+i} \left(\frac{\text{Pens}}{\text{GDP}} \right) &= [\text{Contrib}(\text{ODR}) + \text{Contrib}(\text{EMP}) + \text{Contrib}(\text{BEN}) + \text{Contrib}(\text{ELIG})] + \varepsilon_i, \quad (2) \end{aligned}$$

$$\text{and } \text{Contrib}(X) = \left(\frac{\text{Pens}}{\text{GDP}} \right) \dot{g}_i(X),$$

21. The ratio of 55+ to the working age population is used to take account of the fact that a considerable share of older workers retire before 65.

where \dot{g}_i is the percentage growth rate of the term in brackets and ε_i is the residual from the log linearisation. Average benefits are defined as total pension expenditure in any year divided by the number of beneficiaries. In the absence of information on beneficiaries, the Secretariat assumed that the number of beneficiaries equalled the non-active share of the population aged 55+ for France, Japan, Sweden and the United Kingdom. This approximation for the eligibility ratio leads to an overestimation of the number of beneficiaries and the eligibility ratio and an underestimation in the average benefit. For Italy, the number of pensions, rather than the number of pensioners, was used.

45. To minimise the large residuals which normally appear when linearising a non-linear relationship with large changes, the results were calculated for each five year period and the per cent changes in spending as a share of GDP for each period were added together.

46. Box A.1 provides a list of measures/reforms to pension systems in OECD countries affecting average benefits and the effective age of retirement that have been included in the projections.

Box A.1. Policies affecting average benefits and eligibility country detail

Australia

- Tax-free bonus for those working after pension age.

Austria

- Pension system for civil servants is aligned to a greater extent on the private sector scheme.
- Tightened eligibility requirements for early retirement including:
 - A gradual rise in the pensionable age for early retirement for men from 60 to 61.5 and for women from 55 to 56.5 between 2000 and 2002.
 - Introduction of a bonus/malus – system for early/late retirement.
 - Tightening of conditions for disability pensions.
 - Reduction of widowers' and widows' pensions in case of own income/pension.
- Indexation of pensions according to net wages since 1993.

Belgium

- Indexation of pensions on prices since the early 1980s for the general pension scheme for wage-earners and the self-employed. Some minor real increases are allowed for specific groups.
- Indexation of wage-ceilings to real wages interrupted between 1982 and 1999.
- Gradual rise in the pensionable age of women from 60 to 65 (the same as for men) over the period 1997 to 2009.
- Period used for calculation of full benefits for women increased from 40 to 45 years over the period 1997 to 2009.
- Minimum work history for retirement before the age of 65 under the old-age pension scheme progressively increased from 20 to 35 years over the period 1997 to 2005.
- The age of early retirement under collectively-bargained arrangements raised from 55 to 58 years.

Czech Republic

- Lengthening in the number of years of earnings used to calculate pensions from 10 to 30 by 2016.
- Increase of retirement age.
- Tightening up of conditions for disability pensions.

- Equalisation of widowers' and widows' pension.
- Introduction of an actuarially fair adjustment for early retirement pensions.

Denmark

- A premium paid to individuals working after 62.

Finland

- Reference earnings for calculating benefits increased from last 4 to last 10 years of earnings, phased in by 2003.
- Wages used to calculate benefits are defined net of employees' pension contributions.
- Weight of the wage component in the formula for indexing old-age pensions (65 and over) reduced to 20 per cent.
- Reduction of the rate of accrual of pension rights under early retirement pensions.
- The minimum age for access to the individual early retirement pension raised by 2 years.

France

- Pensions indexed on prices rather than wages.
- Pensions calculated on the basis of best 25 years of earnings rather than 10.
- Minimum contribution period for retirement on a full pension at 60 progressively increased from 37.5 to 40 years.

Germany

- Indexing of pensions to net wages from 1992.
- Temporary indexing of pensions to inflation in 2001 and 2002. From 2002 onwards, a demographic progression factor takes into account the lengthening in average lifetimes at 65.
- Progressive standardisation of retirement ages to 65 over the period to 2004.

Greece

- Maximum replacement rates reduced by 25 per cent.

Hungary

- Weights used for indexing pensions changed to 50 per cent prices and 50 per cent net wages from 2001.
- Shift towards a private arrangement after 2013.
- Increase in the pension age to 63.
- Early retirement benefits reduced.

Italy

- Shift from wage to price indexing of pensions.
- Progressive move to a system where benefits are related to longevity and to contributions.
- Access to old-age pensions and long-service pension tightened.

Japan

- Benefits reduced or contributions increased every 5 years to keep the social insurance pension system in balance.
- Change in indexation from net disposable income to prices.
- Increase in the age at which flat-rate benefits are received from 60 to 65 with a phase in period ending in 2013.

Korea

- Revision in benefit formula resulting in a reduction of replacement rate from 70 to 60 per cent.
- Price rather than wage indexation introduced.

- Age for receiving a full pension progressively increased from 60 to 65 over the period 2013 to 2033.

New Zealand

- Age for receipt of the state pension raised from 60 to 65.

Portugal

- The pension age of women raised from 60 to 65.

Spain

- Progressive increase in the number of years of earnings taken into account for the calculation of benefits from 10 years in 1998 to 15 years in 2004 (Toledo Agreement).

Sweden

- Progressive move to contributions based system, taking account of lengthening lifetimes.

United Kingdom

- Alignment of the pension age of women to that of men (65 years of age).

United States

- Increase in the age for receiving a full pension to 67, phased in over, roughly, a twenty-year period from 2000.

5. Health care, long-term care and other age-related spending

47. As emphasised in the main text, the margins of error surrounding projections of health care spending are much wider than for pensions. Health and long-term care costs will be affected by a range of factors in addition to ageing: technology, increases in supply (hospitals and medical personnel), incentives facing suppliers and patients, changes in price/costs of health care relative to other goods and services and increased underlying demand as incomes rise. While these additional factors have explained the bulk of past increases in spending, there is little consensus on the relative importance of each for the future.

48. In practice, most countries projecting health care have taken the impact of ageing into account by weighting per capita care costs by age/sex groups by the population structure for each five year period. However, Korea (which did not include medical care costs paid under the social insurance system) projected health care costs on the basis of a regression analysis that included only GDP, the number of elderly and a (negative) time trend. This approach appears to have contributed to a relatively small increase in public health care spending over the projection period. The Norwegian approach is based on a model for the production of public services (mostly located in local administration), using Leontief-type fixed coefficients for labor, intermediate inputs and investments weighted according to the age structure of patients.

49. Even among countries using an approach based on per-capita costs per age group weighted by the importance of each age group, the results can differ considerably. This depends on the following factors.

- Belgium, Canada and the Netherlands have included long-term care with health care costs. Their change in spending for these three countries needs to be compared with the total of health care and long-term care spending of the other countries except the United Kingdom, where long-term-care costs do not appear to have been taken into account at all.
- The fineness of the breakdown of costs by age group and by sex varies across countries. For health care spending the Japanese projections only distinguish between persons aged over and under 70, while the Belgian projections are based on a breakdown by 5-year age groups and by sex. Even if the breakdowns were the same, the pattern of costs per capita across age

groups and can differ considerably. For example, the ratio of health and long-term care costs of the over 65 age group relative to the under 65s is around 5.5 in Canada and the Netherlands, while for Belgium it is around 4.

- Countries have taken different approaches to take into the account trends in income, relative prices or technology. This probably explains a good part of the variation across countries as small differences in trends can have a large impact when cumulated over a period as long as 50 years. Some key differences are:
 - Canada, Denmark, and Sweden assume that the costs will rise in line with productivity or wages. The Netherlands set the annual increase at 1.75 per cent with 0.4 per cent added to the growth rate over the period to 2020. The Czech Republic allows per capita health care costs to rise by 3 per cent per annum to 2015 and then by 2 per thereafter (but only 1.5 per cent growth for long-term care).
 - The United Kingdom assumes that both current and capital costs rise in line with real GDP.
 - Belgium has established the impact of different demand and supply factors affecting health care costs using regression analysis. On this basis, health and long-term care costs (adjusted for changing population structure) rise with per capita GDP using an elasticity of 1.1. Japanese health care expenditures rise in line with GDP with an elasticity of 1 for persons over 70 and 0.97 for those under 70. Australia allows for strong relative-price/income/quality effect which explains more than half of the overall 6 percentage point increase over the projection period;
 - For the United States costs are also aligned on GDP per capita, but are allowed to rise more rapidly than GDP (for Medicare up to 2025 and for Medicare through the whole period).
 - Finally the Netherlands allows for “costs of death” in calculating the trends over time in health care costs. Costs per death are the same for all age groups and the share of these costs in total spending by age group is estimated by first multiplying the “cost of death” by the probability of death in that age group. “Recurrent” health care costs for each age group are then estimated by deducting the “death-related” costs from total health care costs. Since the probability of death increases with age, the share of death-related costs in total health care costs increases with the age of the group. Lengthening lifetimes and the associated decline in the probability of death, leads to slower projected growth in overall health care spending as the “costs of death” are delayed.

6. Sensitivity tests

50. Results of the sensitivity tests (presented as a share of GDP relative to baseline) differ across countries depending on the extent to which the changes in assumptions alter spending and output (Table A.13). Comparisons of the sensitivity tests across countries need to be treated with caution. First, the size of the shocks differs across countries for two of the sensitivity tests:

- For the test of higher immigration, the number of net immigrants was increased by 50 per cent relative to baseline. However, with the level of immigration (relative to the total

population) differing across countries in the baseline, the change relative to the baseline varies across countries as well.

- Similarly, in the test allowing a reduction in unemployment to levels experienced in the late 1960s, the starting and end points for unemployment also differs across countries.²³

For both these tests, rough adjustments were made to improve cross-country comparability (shown in columns 2 and 4 of Table A.13):

- For each country the impact of higher immigration on spending was adjusted on the basis of the cumulated immigration over the projection period relative to end-of period population. The adjustment coefficient for each country was calculated as this ratio divided by the average of the ratios of all the countries (8.5 per cent). The reported change in the spending to GDP ratio (Columns 1 and 3 of Table A.13) was divided by this coefficient. While the adjustment narrows the variance, differences across countries remain wide.
- For unemployment, the reported change in the spending relative to GDP was divided by the change in the unemployment rate in percentage points. This approximates the change for each percentage point fall in the unemployment rate. These results for the sensitivity test for lower unemployment suggest that a 1 percentage point reduction in the unemployment rate would reduce total age-related spending as a share of GDP by 0.2 percentage points on average.

51. Second, there appear to be significant differences across countries in the impact of the changes in assumptions.²⁴ These can reflect the institutional arrangements that vary from one country to another. They can also result from different modeling approaches: for example, the degree of feedback between different spending programs and between macroeconomic variables.²⁵ In a few cases, the changes may have been introduced in ways that could affect outcomes. Finally, they result from the differences in the size of age-related spending in GDP in the baseline.²⁶ Some salient features are:

- Aside from immigration and unemployment, cross-country differences in the impact of the change in assumptions on GDP within each test were relatively modest. Key cross-country differences appear to reflect differences in the impact of the sensitivity test on spending.
- Increases in longevity have very different effects across countries. They are particularly low for Italy and Sweden where pensions are adjusted to allow for the longer life-spans. They tend to be largest in Denmark and the Netherlands, which have flat-rate systems. Large increases in other age-related spending (mainly health care) are indicated for Korea and the United States.

22. These differences also reflect the rules agreed in setting the baseline. Belgium, France, and Italy took advantage of the rule that structural unemployment rates could fall by up to one third through the projection period, while Spain reduced unemployment rates to 4 per cent, virtually eliminating any additional impact from the sensitivity test. For these countries, the fall in unemployment rates in the sensitivity tests was less than for most other countries.

23. Certain tests for Korea were difficult to interpret.

24. For example in Belgium and the Netherlands higher unemployment leads to increases in “early-retirement” spending.

25. For example, a country with a large share of age-related spending in GDP will experience a larger impact when the changes are measured in terms of percentage points of GDP for the same per cent change in spending.

- There is relatively little impact from changing assumptions on fertility and immigration on pension spending as most of the additional workers associated with these changes will not reach retirement until after 2050. The increases in pension spending are particularly small for France. For countries projecting other age-related spending components, the larger population (and more young people) leads to higher spending on other age-related components (health care and child-related spending), with the exception of Denmark.
- Reductions in participation rates for older workers and women also have relatively modest effects on spending. This is particularly the case for countries with flat rate systems (Canada, Denmark, the Netherlands and the United Kingdom) but also for the United States. There are falls in other age-related spending in a number of countries, although why this should be the case is not clear.
- For the test of a reduction in productivity growth, spending on pensions tends to move in line with productivity growth (except for the United Kingdom, where there is no change), Italy, Japan, Poland, Spain and the United Kingdom. For other age-related spending, differences reflect the degree to which costs automatically adjust to changes in productivity. For example certain components such as education and health care are not linked to productivity for the Czech Republic and the United States.

7. Method of estimating the impact of alternative policy measures

52. The Section on policy options and Table 7 (Panel B) in the main text examined three alternative policies to offset the impact of ageing on public finances:

- A reduction in the number of people receiving pension benefits (pensioners);
- A reduction in average pension benefits; and,
- Changes in primary surpluses.

53. Calculations of these three alternative policies were calibrated so as to maintain debt constant as a share of GDP at the end of the projection period. The first two policies are measured in term of percentage change in either pensioners or average benefits needed, respectively to achieve this outcome. The third policy alternative indicates the primary surplus that the “typical” country needs to sustain throughout the period 2005-2050 to maintain debt to GDP ratios constant at the end of the period.

54. The exercise assumes that other government spending and revenues remain constant as a share of GDP. Therefore, changes in the primary balance are fully driven by changes in age-related spending. The “non-age-related” primary balance is defined as the initial primary balance in 2005 and is kept constant through the projection period.

55. Primary balances plus interest payments on previous debt determine current deficits. Debt is calculated as the debt in the previous period plus the current deficit. The long-term interest rate used in the calculations was 4 per cent.

56. Projections for the following variables were drawn from countries submissions: pension spending – defined as the product of average pensions, A_b , and the number of pensioners, N ; other age related spending (OARE), including health care and long-long term care; other government spending (OGE)

(excluding debt servicing), and government revenue as the share of GDP. The primary balance (positive if in surplus) is defined as the difference between revenues and spending:

$$pb_j = revenues_j - spending_j = (tr_j * GDP_j) - (N_j * Ab_j + OARE_j + OGE_t) \quad (3)$$

Where tr is the tax rate (defined as the share of total revenues in GDP), and GDP is defined as the product of average productivity and total employment.

57. Debt and debt-interest payments will vary with changes in pension spending and primary surpluses as different policies are assumed. Because projections are presented at 5-year intervals, debt and debt-interest payments were calculated on the basis of a linear interpolation of primary surpluses, using the following formulas:

$$debt_{t+5} = (1+r)^{5-1} debt_t - \sum_{i=0}^{5-2} (1+r)^i pd_{t+(5-1)-i} - pd_{t+5} + ip_{t+5} \quad (4)$$

$$ip_{t+5} = r * (1+r)^{5-1} debt_t - \sum_{i=1}^{5-1} r * (1+r)^{i-1} pd_{t-i} \quad (5)$$

Where ip stands for interest payments, defined as $ip_t = r * debt_{t-1}$, and r stands for the interest rate.

58. The policy goal is to reduce the debt to GDP ratio in 2050 to its level in 2005 either by reducing pensioners or average benefits, or by increasing primary surpluses. Therefore, the debt to GDP ratio in 2050 has to be reduced by:

$$\left(\frac{debt}{GDP} \right)_{2050} - \left[\left(\frac{debt}{GDP} \right)_{2050} - \left(\frac{debt}{GDP} \right)_{2005} \right] = \left(\frac{debt}{GDP} \right)_{2050,new} = \left(\frac{debt}{GDP} \right)_{2005} \quad (6)$$

59. Using equation (4) above, the debt in 2050 that results from implementing a specific policy measure can be defined as:

$$debt_{2050,new} = (1+r)^{44} debt_{2005} - \sum_{i=0}^{43} (1+r)^i pd_{2049-i,new} - pd_{2050,new} + ip_{2050} \quad (7)$$

60. A reduction in the number of pensioners ($\Delta N = y = N_{new} - N_{old}$) has three inter-related effects. First, pension spending is reduced. Second, government revenues increase under the strong assumption that those who do not retire continue to work. Third higher employment leads an increase in GDP. That is:

$$pb_{j,new} = pb_{j,old} + y * [tr_j * Av.prod_j + Ab_j]$$

where tr is the tax rate $Av. prod$ stands for average productivity and Ab for average benefits.

$$GDP_{t,new} = (E_t + (-\Delta N)) * Av.prod_t = GDP_{t,old} - \Delta N * Av.prod_t \quad (8)$$

where E is employment.

Using (6), (7) and (8), the required reduction in the number of pensioners to reduce the debt to GDP ratio in 2050 to its 2005 level is equal to:

$$\Delta N = \frac{B * GDP_{2050}}{A * Av.prod_{2050} + (tr_{2050} * Av.prod_{2050} + Ab_{2050}) + \sum_{i=0}^{43} (1+r)^i * (tr_{2049-i} * Av.prod_{2049-i} + Ab_{2049-i})} \quad (9)$$

Where A is the debt to GDP ratio in 2005 and B is the difference between the debt to GDP ratio in 2050 and 2005

61. *Reducing average pension benefits* affects only pension spending. The savings in pension outlays are equal to the number of pensioners per unit of pension benefits reduced. The required change is given by:

$$\Delta Ab = \frac{B * GDP_{2050}}{\sum_{i=0}^{43} (1+r)^i N_{2049-i} + N_{2050}} \quad (10)$$

62. Alternatively countries can offset the impact of ageing by running high enough primary surpluses throughout the period from 2005 to 2050. The increase in the non-age-related primary surplus relative to GDP that has to be sustained through the entire period is given by:

$$T = \left(\frac{\text{increase in primary surplus}}{\text{average}(GDP_{2005} - 2050)} \right) = \frac{B * GDP_{2050}}{\sum_{i=0}^{43} (1+r)^i + 1} / \text{average}(GDP_{2005} - 2050) \quad (11)$$

63. Table 7, Panel B shows that the percent reduction in pension beneficiaries required to maintain debt constant relative to GDP is lower than the required percentage reduction in average pensions, reflecting the feedback effects of lower pension payments, higher tax revenues and higher overall output. To better judge the magnitudes of a change in the number of beneficiaries, rough approximations suggest that a reduction in debt of 10 percentage points of GDP can be achieved by a 2-month delay in the average age of retirement over 45 years.²⁷

64. The differences in the required change between the two policy measures are likely to be overstated. First, it is assumed that a reduction in average benefits affects all pensioners equally. Second, no allowance is made for the fact that a longer period of employment could raise the average benefit of individuals. Finally, in the simulation of a reduction in the number of beneficiaries, it is assumed that those who do not retire continue working and pay taxes. However, the amount of tax paid will depend on the differences in tax rates between employees and the retired and their respective income levels. In this exercise the increase in tax revenues was assumed to be half because retirees also pay taxes, although at a lower rate.

65. Table 7, Panel B also shows that alternatively the “typical” country could offset the impact of ageing by running a moderate primary balance of 1 percentage point over the baseline 2½. However, these surpluses need to be sustained over the entire period. Averages hide important differences across countries reflecting different initial fiscal positions and the size and timing of ageing. Using the same methodology as for the “stylised” country, Table A.14 below shows primary surpluses (and the change in the primary surplus relative to the baseline) that each country needs to achieve:

26. Assuming a proportional distribution of retirees across the age spectrum from 63 to 79, that is over 16 years, there is then 100/16=6.25 per cent of retirees in each year interval. Then, if a reduction of 6.25 per cent in pensioners is equivalent to a year, a 1 per cent reduction in pensioners is equivalent to 2 months.

- A debt to GDP ratio at the end of the projection period unchanged from the beginning (2005) (column 4); and
- A reduction in the debt to GDP ratio to zero by the end of the period (column 5).

These calculations take into account the increase in age-related expenditure (column 1).

66. In making these calculations, tax revenues associated with large tax-sheltered pension schemes were included for Canada, Denmark and the Netherlands. Debt as a share of GDP was taken from the *Economic Outlook* (June 2001) where different from the share provided in countries' submissions. Since France, Germany, Italy, Poland and Spain do not provide projections of age-related spending other than age-related pensions, they are treated separately. Table A.14 (panel B.1) shows the primary surplus when only old-age spending increases are considered and other age-related expenditures are assumed to move in line with GDP over the projection period. However, countries which make projections of other age-related spending, have an additional increase in total age-related spending of around 3 percentage points of GDP. Therefore, Table A.14 (Panel B.2) shows the primary surplus when the average increase in other age-related spending of countries in panel A is added to the projected increase in old-age pension spending. As a result, France, Italy, Spain, and Germany to a lesser extent, have to run the highest primary surplus to offset the impact of ageing, together with the Netherlands and Belgium.

67. The results of these calculations for individual countries are open to wide margins of uncertainty. As shown in Table 7, small change in assumptions concerning interest rates, the levels of debt and the primary deficit at the beginning of the period on debt at the end of the period. Nonetheless, they serve to illustrate some of the factors explaining the cross-country differences in the need for fiscal restraint. For example:

- Italy and Spain need to run similar primary surpluses even though Spain has a large increase in age-related spending while Italy has virtually none. This reflects the cost of financing the high level of debt in Italy;
- Despite the largest increase in age-related spending, Norway does not need to run one of the largest primary surpluses to achieve a zero level of debt by the end of the period because it has a large public sector net asset position;
- In addition, the timing of ageing can also have important effects. The Czech Republic has a larger increase in age related spending than Denmark and both have broadly similar debt positions. Nonetheless, Denmark needs to run a higher primary surplus over the 50-year period because the increase in age-related spending occurs much earlier in Denmark than in the Czech Republic.²⁸

²⁸

While the increase in age-related spending reaches its maximum in 2030 in Denmark, 5.9 percentage points of the overall spending increase of 6.9 points in the Czech Republic occurs after 2030.

Table A.1. Population projections : Total Population and selected ratios
(Level and average annual growth rate for population and level for dependency ratios at the end of the sub-period)

		2000	2000-35	2035-50	2000-50			2000	2000-35	2035-50	2000-50
Australia	Total Population	15,430	0.88	0.26	0.69	Japan	Total Population	126,892	-0.40	-0.78	-0.46
	Youth DR	11.62	9.51	9.21			Youth DR	33.0	32.21	35.52

1. Youth dependency ratio is those individuals aged (0 to 19) as a share of the working-age population (20-64).

2. Old-age dependency ratio is those individuals aged 65 and over as a share of the working-age population (20-64).

Source: OECD.

- 1) Does not include countries presenting data on old-age pension spending only
2) Total pension spending includes other age-related spending which does not fall within the definitions. This represents 0.9 per cent of GDP in 2000 and rises by 0.1 percentage point in the period to 2050.
3) Total includes other age related spending not classifiable under the other headings. This represents 6.3 per cent of GDP in 2000 and increases by 0.2 percentage points from 2000 to 2050.
4) Total includes old-age pension spending and "early retirement" programmes only.
5) "Early retirement" programmes only include spending on persons 55+
6) OECD average excludes countries where information is not available and Portugal which is less comparable than other countries.
7) Portugal provided an estimate for total age-related spending but did not provide expenditure individual spending components other than old-age pensions.

Table A.14. Primary balances needed to offset the impact of ageing, 2005-2050

(Percentage points of GDP)

	Total primary surplus ³				
	Increase in age-related spending ¹	Non-age-related primary balance ²	Debt to GDP ratio in 2000	Keep debt constant at its 2000 level by 2050	Reduce debt to zero by 2050
<i>A. Countries projecting most age-related spending components</i>					
Belgium	5.1	7.1	103.0	4.2	5.3
Canada	7.1	9.0	66.0	3.7	4.5
Czech	6.9	-2.4	18.1	1.6	1.8
Denmark	5.7	2.7	26.4	3.7	4.0
Finland	8.5	3.4	-32.6	2.5	2.1
Japan ⁴	3.0	-2.8	50.7	3.6	4.1
Korea	8.5	1.3	-31.0	3.9	3.5
Netherlands	9.9	2.9	44.4	6.1	6.6
New Zealand	8.4	1.0	0.6	2.9	2.9
Norway	13.5	7.8	-61.6	4.6	4.0
Portugal	4.5	-1.2	1.3	3.4	3.4
Sweden	3.2	0.9	5.7	1.0	1.1
UK	0.2	1.1	38.5	0.8	1.2
USA	5.6	3.4	41.8	2.7	3.2
<i>B. Countries projecting old-age pension spending only⁵</i>					
<i>1. Other age related spending increases in line with GDP</i>					
France ^{4,6}	4.2	-1.6	42.5	4.2	4.9
Germany	5.0	1.8	41.8	2.5	2.9
Italy	-0.1	5.2	98.7	3.0	4.0
Poland	-2.6	-1.8	-4.0	-2.8	-2.8
Spain	8.0	3.2	43.0	2.9	3.3
<i>2. Other age related spending increases according to the average increase in countries in Panel A</i>					
France ^{4,6}	7.5	-1.6	42.5	5.9	6.6
Germany	7.9	1.8	41.8	4.3	4.7
Italy	2.7	5.2	98.7	4.9	5.9
Poland	0.3	-1.8	-4.0	-1.0	-1.0
Spain	10.9	3.2	43.0	4.8	5.2

1. Sum of the increase projected in old-age pensions, programs permitting early withdrawal from the labour force, and other age-related spending such as health care and care for the frail elderly, family benefits and education.

2. Primary balance implicit in the projection exercise when age-related expending remains constant relative to GDP at its 2005 level over the projection period. Non-age-related spending and total revenues remain constant relative to GDP.

3. Primary surplus needed to run from 2005 until 2050 to either.

4. Countries not providing projections on net interest payment or debt. These components were calculated by the Secretariat.

5. These countries do not report projections on other old-age spending and therefore they implicitly assume that health care and care for the elderly will evolve in line with GDP (Panel B.1). However, to improve comparability, the Secretariat recalculated the primary surplus assuming that other age-related spending increases according to the average increase in the countries in panel A (Panel B.2): 2.9 percentage points by 2050.

6. French projections only cover the period from 2000-2040.
